- 2. Tests of the Standard Model
- 3. Shortcomings
- 4. Conclusions

Overview

- What is the Standard Model?
 - What does it describe?
 - What does it need as inputs?
- Experimental tests
 - Verification of theory
 - Adding the missing parameters
 - Check internal consistency
- Shortcomings
 - Experimental problems
 - Philosophical problems

See also pp plenaries and parallel sessions for more details

3. Shortcomings

4. Conclusions

What does the Standard Model describe?

SM describes matter – force interactions;

- 12 types of matter particle (fermion)
- 3 forces, mediated by force carrying particle (boson)

We use the SM to predict experimental observations

space

Quarks (3 generations) Leptons (3 generations) Force carriers

Constructing the Standard Model

SM is a field theory. Describe force - matter interactions by Lagrangians

Lagrangian L obeys local gauge invariance

Doesn't change as a function of space and time: $\Psi \rightarrow e^{-i\theta(x,t)}\Psi$

Consequence that bosons must be massless

Each force described by L of similar form (details of F, D, Ψ vary)

4. Conclusions

Constructing the Standard Model L_{SM} = L_{EM} + L_{WEAK} + L_{STRONG}

EM force	Weak force	Strong force
Electric charge (1)	Weak charge (2)	Colour charge (3)
Massless photon	Massive W [±] ,Z	8 massless gluons
Coupling g	Coupling g _W	Coupling g _s

Value unknown/ not predicted

3. Shortcoming

4. Conclusions

Constructing the Standard Model L_{SM} = L_{EM} + L_{WEAK} + L_{STRONG}

EM force

Abelian

Only charged particles couple

Value unknown/ not predicted Weak force

Non-abelian

Only left handed particles couple

quark mixing (3 generations, CP)

Neutrino mixing (3 generations, CP)

Strong force

Non-abelian

Only quarks couple

Constructing the Standard Model L_{SM} = L_{EM} + L_{WEAK} + L_{STRONG} + L_{HIGGS}

Bosons are **massless** in SM theory

Introduce Higgs field (m_H , value of Higgs potential v):

Couples to particles to give mass (amount ~ coupling strength)

Keeps Lagrangian invariant

Consequences:

Unifies weak and electromagnetic forces

Massive Z is mixture of massless em + weak bosons Relates Mw, Mz and weak, electromagnetic couplings: $\tan \theta_W = g_W / g$ $M_W = M_Z \cos \theta_W$ (SM good at predicting relations)

Constructing the Standard Model L_{SM} = L_{EM} + L_{WEAK} + L_{STRONG} + L_{HIGGS}

Other considerations:

• Theory must be renormalisable

• Force strength "runs" with energy

EM: charge screening

Weak/Strong: boson self interaction alters apparent charge

- Although theory is easy to write down, it's less easy to use
 - Most tests are of electroweak sector

4. Conclusions

Test assumptions
 Measure parameters

- 3. Test predictions
- 4. Check consistency

Testing the SM

- 1. Test any assumptions we've made
- 2. Measure unknown parameters in different ways and check consistency
- 3. Compare predicted quantities to measurements
- 4. Check internal consistency of entire SM framework

4. Conclusions

1. Test assumptions

2. Measure parameters

3. Test predictions

1. Experimental 2. Philosophical

Any more info from SM?

Always possible Higgs could be heavier if assumptions in SM fit incorrect

But m_H < 1 TeV or predicted WW scattering cross-section starts to violate unitarity

If we don't see Higgs at LHC then:

it doesn't exist

or it's too heavy to make ..

If no Higgs with mass < 1 TeV there must be **New Physics** to keep WW scattering finite.

4. Conclusion

1. Experimental 2. Philosophical

Experimental disagreements?

NuTeV $\sin^2\theta_w$ (~ 3 σ)

Extract from ratio of neutral:charged v nucleon couplings

New Physics? (eg. Z', new fermions)

Or analysis? (uncertainties in pdfs, radiative corrections)

Phys. Rept. 427 (2006) 257

4. Conclusions

Experimental Philosophical

Experimental disagreements?

Couplings of b quarks?

 A_{fb} measured vs. SM prediction (2.8 $\sigma)$

No identified experimental explanation

Assumed to be a fluctuation

4% of the universe?

SM with electroweak and strong interactions only describes 4% of the universe

Source: Robert Kinshner narce: NASA/WMAP Snience Team Dark matter?

Try Supersymmetry

Lightest supersymmetric particle is a dark matter candidate (massive and unobservable)

1. Overview 2. Tests of the Standard Mode 3. Shortcomings

Experimental Philosophical

Why 3 forces? 3 generations?

What if there is 1 force, which fractured at high energy to give what we see today?

Forces "run" with energy and don't agree at high energy

New Physics (eg. SUSY) can modify their evolution to join up \rightarrow unification?

Particles – why so many ingredients of matter?

Why are their masses so different?

1. Overview 2. Tests of the Standard Mode

3. Shortcomings

. Conclusions

Experimental
 Philosophical

And finally

Gravity

Can't describe it in SM

Can include it in string theory – not very testable

Large extra dimensions could be observed at LHC

CP violation

Consistent picture in SM but insufficient to explain matter – antimatter asymmetry of the universe

? Answer lies in new physics?

Many open questions not addressed by the SM

Conclusions

- Standard Model is the theoretical framework used to describe matter force interactions
- Incomplete doesn't explain all of the universe
- Remarkably successful

Conclusions

- experimental tests so far very compatible with predictions
- Last piece of the jigsaw remains to confirm or deny existence of the Higgs at the Tevatron or LHC.

Extra

g-2

Anomalous magnetic moment of the muon

 $a_{\mu} = \frac{1}{2}(g-2)$

- non zero value due to higher order corrections
- Measure spin "wobble" in magnetic field (v. accurate)

 $\begin{array}{l} a_{\mu} = (11\ 659\ 208.0\ \pm 6.0)\ x\ 10^{-10} \\ \text{cf.}\ (11\ 658\ 471.81\pm 0.02)\ x\ 10^{-10} \\ \text{EWK:}\ (15.4\pm 0.2)\ x\ 10^{-10} \\ \text{Vac.}\ :\ (692.2\pm 9.2)\ x\ 10^{-10} \\ \text{Light:}\ (12.0\pm 3.5)\ x\ 10^{-10} \end{array}$

 Investigations / new e⁺e⁻ measurements ongoing.

The results from E821 for the muon anomalous magnetic moment.

Non-peturbative

contribution can be normalised from measurements of $e^+e^- \rightarrow \pi^+\pi^-$ (3 σ) or $\tau^+\tau^- \rightarrow \pi^+\pi^-$ (ok)

g-2 for electron

Anomalous magnetic moment of the electron $a_e = 1/2(g-2)$ - Most precisely measured SM parameter $-a_{e} = 0.001 \ 159 \ 652 \ 180 \ 85(76)$ $\Rightarrow \alpha^{-1} = 137.035\ 999\ 710(96)$ Corrections: QCD: 1.671(19) x 10⁻¹² Weak: 0.030(01) x 10⁻¹² QED test.

Tests over different energy scales

Predict quantity with high energy measurements – extrapolate to low energy and compare.

Atomic parity violation in caesium

Extract weak charge Q_W(proportional to Z couplings, no. protons, no. neutrons)

Measure -72.74 ± 0.46 cf. SM -72.91 ± 0.03

Moller scattering with polarised electron beam (E-158)

Extract $\sin^2\theta_W = 0.2333 \pm 0.0015$ cf. 0.2314 ± 0.0001 nuTeV extraction of sin²θ_W ~ 3σ different
