

# CERN PS Irradiation plans for large area sensors

Sheffield: R.French

QMUL: G.Beck, A.Martin, J.Morris,  
F.Gannaway, J.Mistry

Liverpool: G. Casse, P. Dervan

CERN: M. Glaser

# OUTLINE

- Obvious need to test large area sensors under bias and with field across the AC dielectric.
- Need to test sensors + hybrid, with probably reduced functionality of the hybrid (might be difficult to read out, but biasing and powering could be possible)
- Likely need to test other mechanical parts.

# The HPK ATLAS07 mask layout

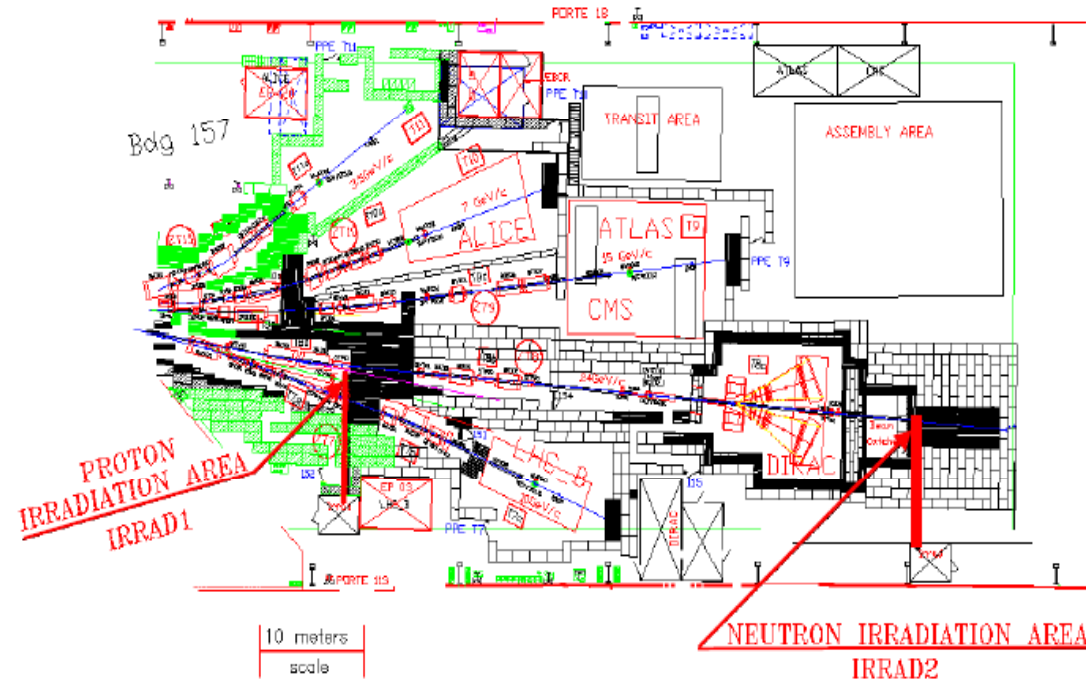

# Where?

- We are well equipped for irradiating  $1 \times 1 \text{cm}^2$  sensors at the CERN (p), Karlsruhe (p), KEK (p), Ljubljana (n) (note, hundreds of these HPK sensors with different p-stop/spray geometries have been, are being or will shortly be irradiated).
- The dimension of the full-size samples ( $10 \times 10 \text{cm}^2$  + mounting frames + services) will not allow irradiations in the neutron facilities traditionally used. Need high energy protons to efficiently irradiate through the hybrid. CERN-PS seems to be suitable for the task, it has been used efficiently for the irradiation program of the present SCT.

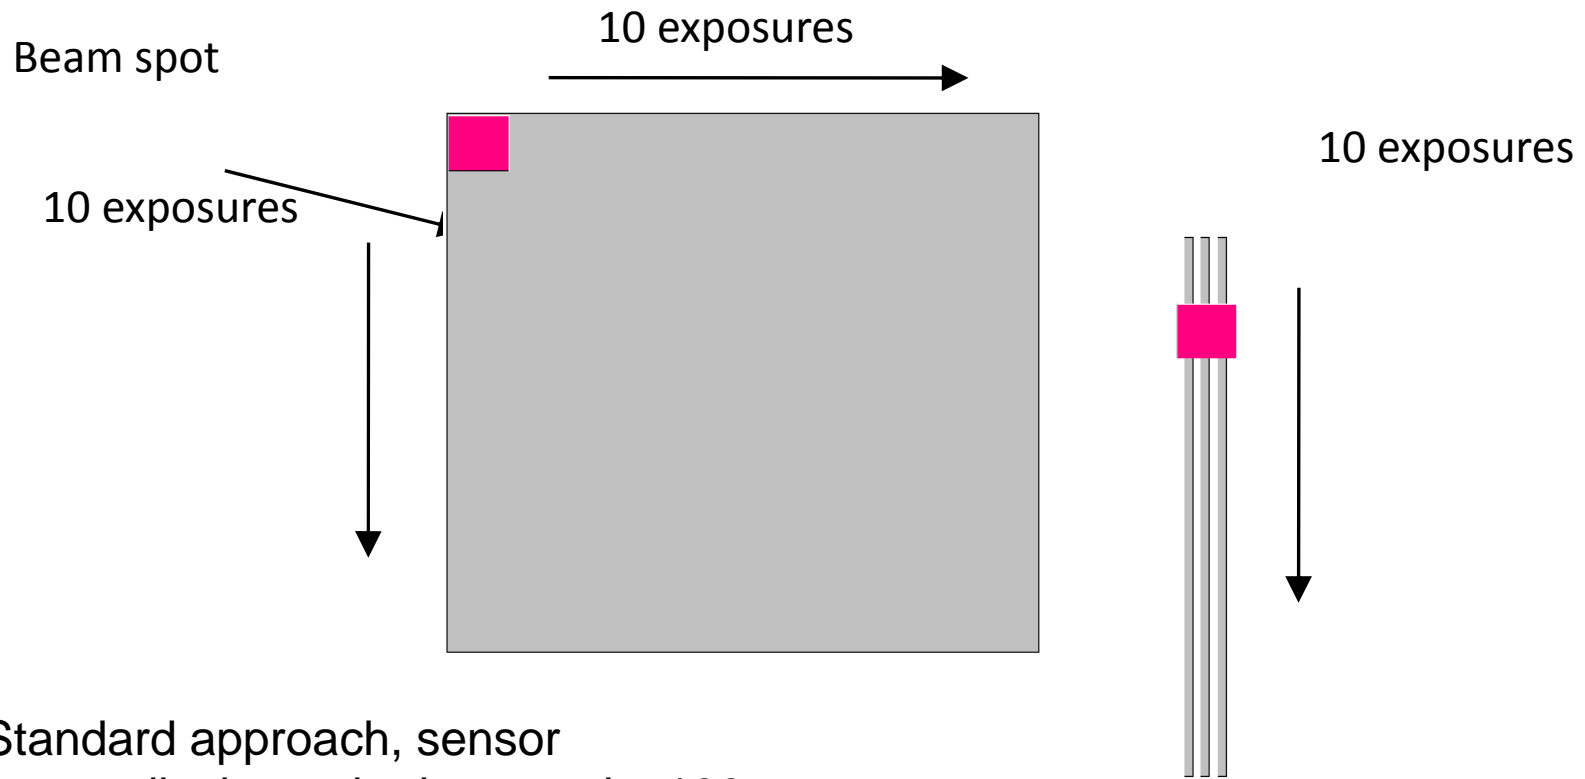

# CERN PS Infrastructure

- 2009 Programme will use the existing IRRAD 5 facility located in the east hall which consists of:
- Linier scanning table (X-Y parallel bedways) placed on SKF telescopic foot (Z with 700mm of adjustment).

- Power from CAEN supplies and most equipment as per 1997 irradiation set up with refurbishment.
- Cables from previous programme will need replacing and redundancy adding for increased RO channels and additional switching matrixes.
  - Provision for in-line connector at 1m away from beam to enable radiation damaged cable changeover.

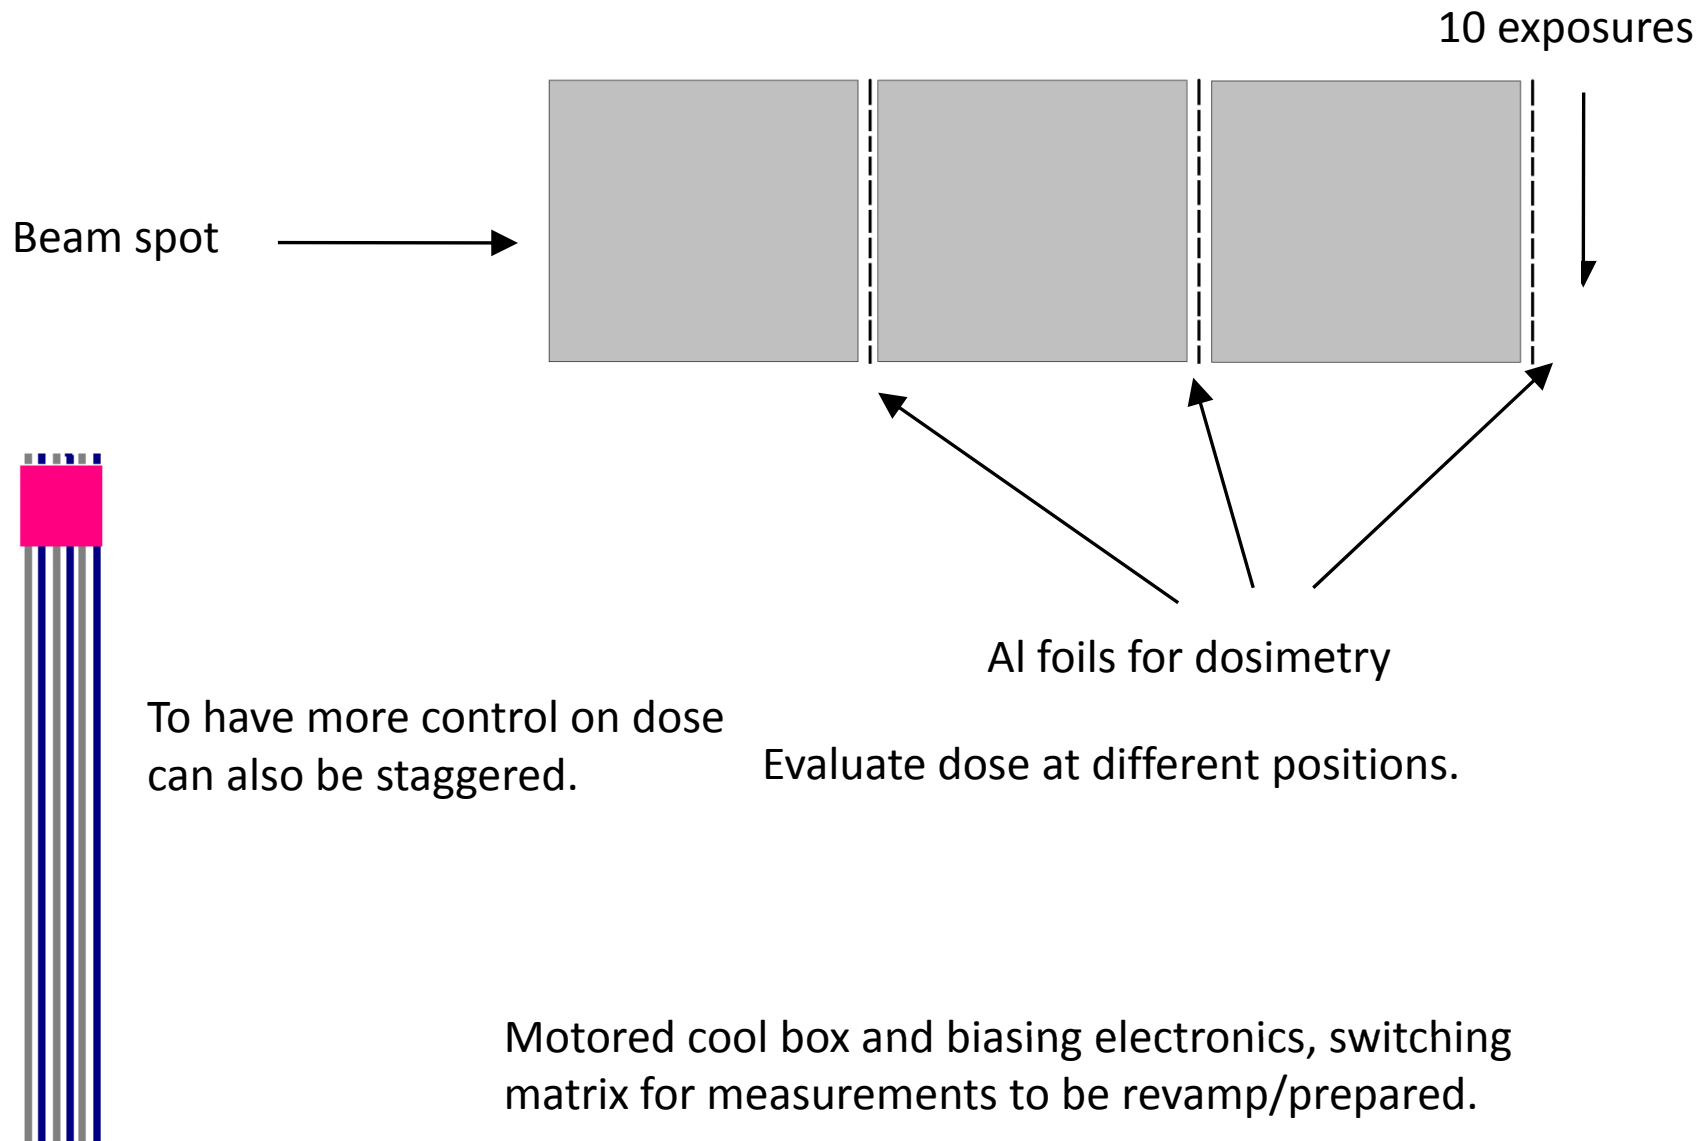

Problem: qualification fluence is now up to  $1 \times 10^{15} n_{eq} cm^{-2}$ . The devices are  $10 \times 10 cm^2$ , the CERN-PS flux about  $1-3 \times 10^{13} p/hour/cm^2$ , with a beam spot of about  $1 cm^2$ . So, to cover the entire surface we would need 100 exposures to final dose, with an anticipated irradiation time is  $\sim 400-140$  days!!  
Need at least a factor of 10 reduction in time.

Standard approach, sensor perpendicular to the beam axis, 100 exposures.

New proposal: sensor parallel to the beam axis, 10 exposures.

How many detectors is possible to irradiate? Lining up detectors for irradiation could be possible.

## Verify radiation hardness (to SLHC fluence) of full-size sensor with surface glued hybrid

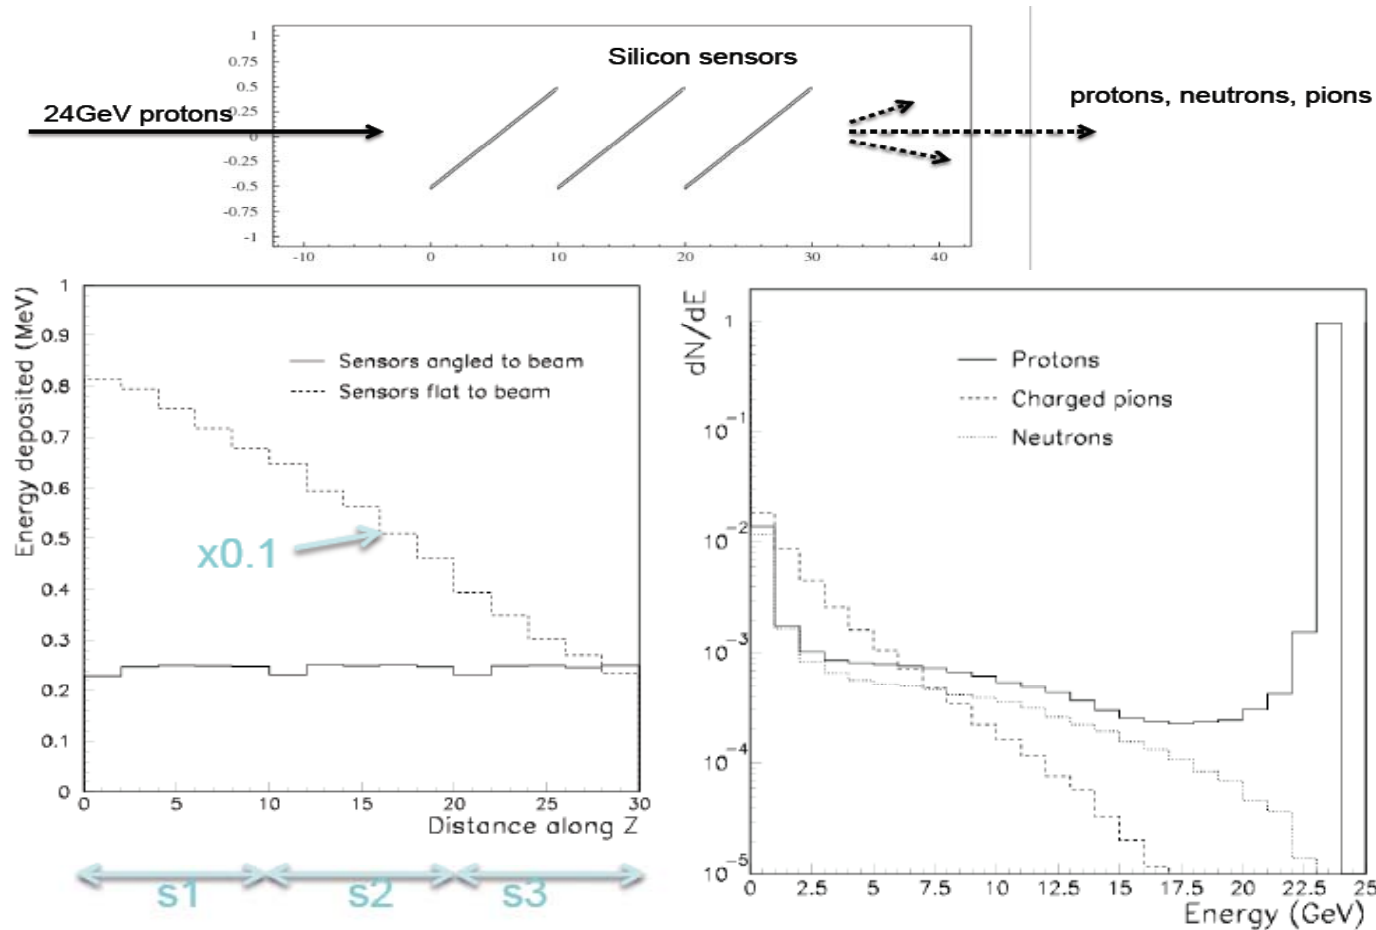

Need bias for realistic electric fields during irradiation  
(surface charge effects) =>

- reverse bias,  $\sim 200\text{V}$  could be sufficient.
- metal->strips: daisy-chain R/O pads + bias to  $\sim 1\text{V}$ .

Sensors Demountable: clamp in G10 pcb frame (+ a few wire bond connections) => minimal sensor mounting: allows removal/re-configuring post irradiation.

# FLUKA sensor angle simulations

Ian Dawson

Sensors (S1,2,3) placed in parallel to beam Z axis

Tilted sensors effectively reduce proton path from Z=300mm =>10mm

## Irradiation of Full size sensors to $10^{15}/\text{cm}^2$ neq.

- T7 extracted proton beam, profile  $\sim 1 \times 1 \text{ cm}^2$ . Flux about  $1\text{-}3\text{E}13 \text{ p/hour/cm}^2$
- Achieve Fluence in 2 week beam period by aligning sensors parallel to beam . . .
- . . . at small angle to horizontal to reduce secondary effects but maximise use of beam.
- 50cm long table + thermally insulated box, scanned horizontally through 10cm.
- Space for maximum of three  $10 \times 10 \text{ cm}^2$  sensors + some passive materials.

**Schematically (side view):**

Three motors:

- 1 Foot elevator for y positioning
- 2 x scanning motor
- 3 theta angle motor for alignment to beam axis using RPC information

## How to Cool Sensors?

- Irradiated Sensor at 200V bias, will dissipate 1W if at -10C and 3W at 0C.
- Single Hybrid Finger (20 x current ABCN) dissipates ~8W clocked and ~10W (during read-out) => difficult task for gas to be chilled and blown to remove heat from a sensor + integrated hybrid.
- Conductive Cooling:
  - Would require good thermal contact to back of sensor + in-board (in-beam) coolant: similar to stave concept
  - Liquid Coolant: Note that in/close to beam Commercial Anti-Freeze subject to polymerisation!
  - Plus dry nitrogen atmosphere.
- Chilled N2 Gas
  - non-contact but inefficient (1999: problems with stability of 6W *module*). Aim for similar system, but with faster, re-cycled flow.

Some simple empirical trials (in progress) at QMUL:

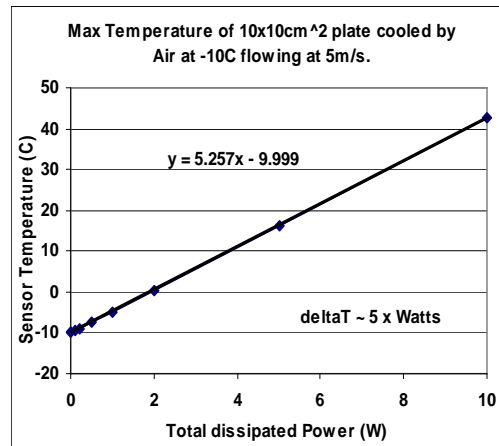

# Sensor cooling!

Two viable alternatives under scrutiny:

Tilted sensor used as a cooling fin, circulated cold glycol (Hakke chiller) and blown N2 previously gave ~ -10°C at box.

*Can we improve the efficiency?*

Cooled sensor mount similar to Stave

Calculating the exact cooling power required for higher energy running is not trivial.

Selection of cooling method is now a difficult choice – pitfalls with each alternative.

Speedy construction and commissioning time plus reliability throughout PS runs is the deciding factor.

## Ducted Fast-Flow Gas Cooling (QMUL)

Room Temperature test!

10x10 cm<sup>2</sup> Aluminium sheet /Kapton heater sandwich in Duct (16cm x 8cm Perspex)

Measure air flow (hot-wire anemometer) + plate and air Temperature (radiometric).

### First Look:

Fan supply: 10V

Air Speed: ~ 2.4 m/s

Max Plate Temp: ~ 1.2C/W  
(linear, 0-10W)

Local Increase in Air Temp ~ 2C at  
10W.

<10% degradation when 2mm  
high frame (as pcb) added to  
plate.

# Gas Circuit

From above: Fast Flow seems adequate for sensors (if 1.3 C/W holds at -10C).

But cannot use:

Bottled Gas => Heat Exchanger => Flow across Sensor => Vent to Surroundings.

(2m/s x 5 cm high x 40cm wide (3 sensors) => 1 Nitrogen bottle every 4 minutes!)

+ enormous cooling power from Chiller.

Investigate possibility of a nitrogen compressor in the area.

In progress at QMUL:

- Explore Sensor cooling dynamics (flow cross-section, velocity)
- Devise:
  - Gas Circulation +Top Up (to maintain acceptable Relative Humidity?)
  - Effective gas chiller: liquid chiller out of beam + Heat Exchanger close to box).

## Also to be done:

Cool-box aligning software, scanning software, bias and monitoring hardware switching matrix for measurements to be revamp/prepared /software.....

Timescale: April will start irradiation. Unlikely to be ready for installation then, but aim is to be in for the summer campaign!
